

Anno Accademico 2007-2008

Laboratorio di Tecnologie Web

Sviluppo di applicazioni web  
primi passi: HTML

<http://www-lia.deis.unibo.it/Courses/TecnologieWeb0708/>

# Just to revise...

---

## > Java SDK

- <http://java.sun.com/javase/downloads/index.jsp>

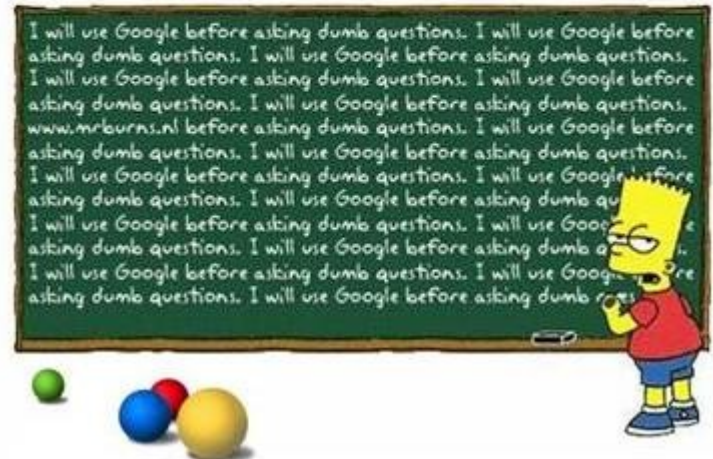

## > Eclipse IDE

- <http://www.eclipse.org/downloads/>

## > Troubleshooting

- <http://www.google.com/>

# Java EE web applications

---

> Java EE architecture:

- **business logic is organized into reusable components**
- Java EE servers provide **underlying services** in the form of a **container for every component type** (security, transaction management, naming, persistence, ...)

> Before a component can be executed, it must be...

- compiled in the same way as traditional Java programs
- assembled into a Java EE application (well formed and in compliance with the Java EE specification)
- deployed to its container

> JEE components are **run and managed by the Java EE server**

- a JEE server realizes the runtime portion of the Java EE framework

# Java EE components

> The Java EE specification defines the following Java EE components:

- **Application clients** and **applets** are components that run on the client.
- **Java Servlet**, **JavaServer Faces (JSF)**, and **JavaServer Pages (JSP)** technology components are web components that run on the server.
- **Enterprise JavaBeans (EJB)** components (enterprise beans) are business components that run on the server.

# Tomcat – A JEE Web server

---

- > Provides a **Servlet** and **JSP** container.
- > Just download and explode it
  - <http://tomcat.apache.org>
  - <http://www-lia.deis.unibo.it/Courses/TecnologieWeb0708/materiale/laboratorio/applicazioni/apache-tomcat-5.5.20.zip>
- > Tomcat structure
  - **webapps**: where to deploy your web applications
  - **conf**: configuration files (e.g., configure tomcat users: the admin)
  - **bin**: launch and shutdown scripts
  - **logs**: log files (e.g., *catalina.out*) will be placed here
    - create this directory if it is not there
    - inspect catalina.out file in case of troubles
- > Launch Tomcat
  - Set (and export, in Linux) your JRE\_HOME environment variable
  - <http://localhost:8080>. Ok. It works.

# Web application structure

## > Web pages

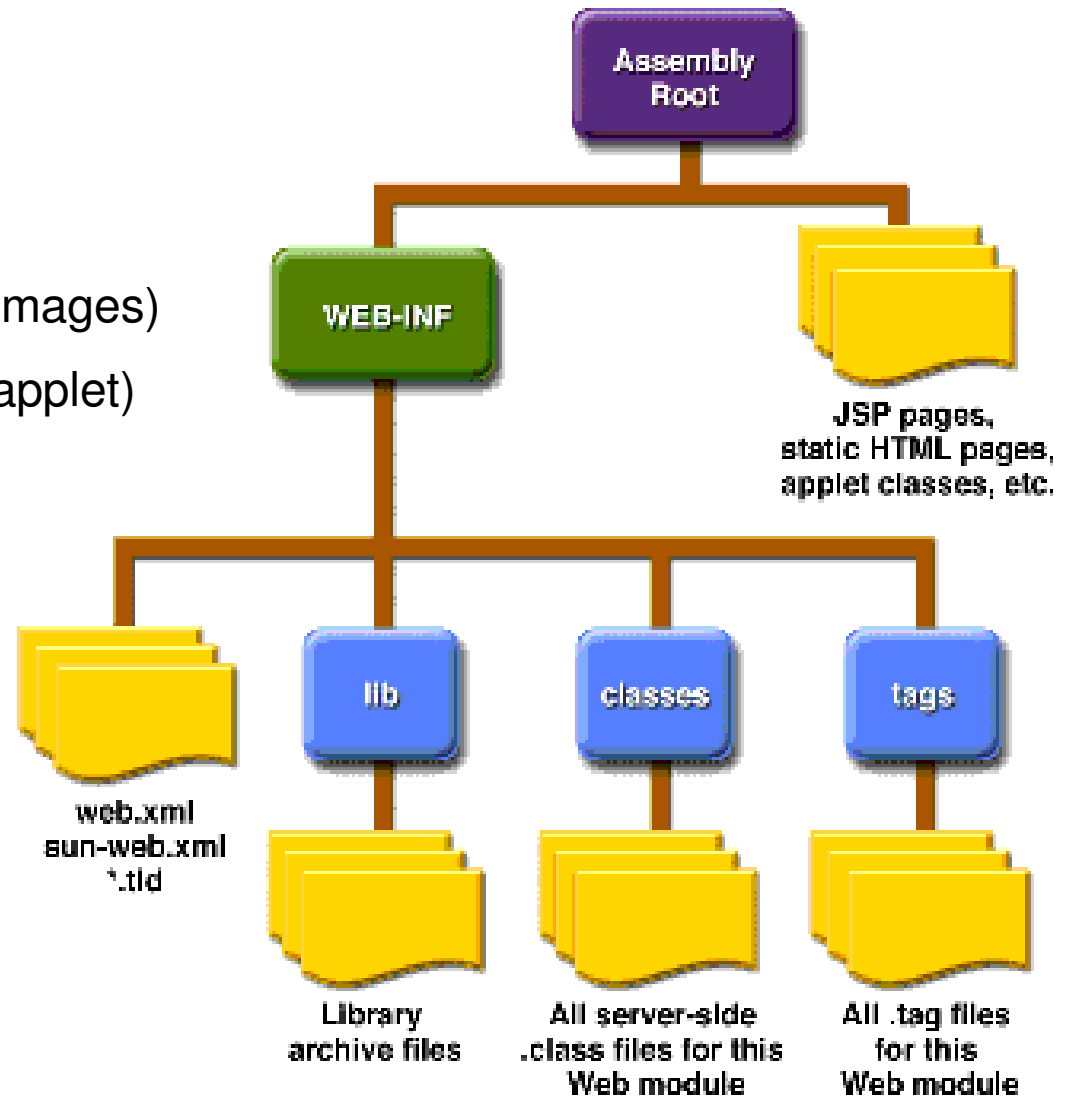

- HTML and JSP pages
- CSS and Javascript
- Static resources (e.g., images)
- Client-side code (e.g., applet)

## > Deployment descriptors

- security constraints
- component aliases
- resource mapping
- ...

## > Server-side code

- classes
- libraries

# Web application structure

---

- > The top-level directory of a web module is the document root of the application.
  - web pages, client-side classes and archives, static web resources
  - /WEB-INF/ subdirectory:
    - *web.xml*: the web application deployment descriptor
    - tag library descriptor files
    - *classes*: server-side classes (e.g., Servlets, utilities and JavaBeans)
    - tag files, which are implementations of tag libraries (later on...)
    - *lib*: JAR archives of the libraries server-side classes depends on
  - application-specific subdirectories (that is, package directories) in either the document root or the /WEB-INF/classes/ directory.
  
- > A web module is portable across different JEE servers and can be either deployed as an unpacked file structure or packaged in a JAR file known as a **web archive (WAR)** file.

# Web application development

---

The process for creating creating, deploying, and running a web application is different from that of traditional stand-alone Java classes:

- 1) Develop the web component code and resources (e.g., HTML pages)
- 2) Develop the web application deployment descriptor
- 3) Compile the web application components and helper classes referenced by the components
- 4) (optionally) package the application into a deployable unit
- 5) **Deploy** the application into a web container
- 6) Access a URL that references the web application, via the browser

# A simple web module to publish HTML pages

> Download the template project you can find at

<http://www-lia.deis.unibo.it/Courses/TecnologieWeb0708/materiale/laboratorio/esempi/TemplateWebapp.zip>

> Import the project into your Eclipse workspace

- File → import → Existing project into workspace → Select archive file..
- *index.html* is already in place

> Set up application and environment specific property files

- `${jdk-home}` is the path to your JDK (> 1.5) installation
- `${appserver.home}` is the path to your Tomcat installation
- properties can be defined in terms of other properties

> ANT targets let deploy the module automatically

- ...provided you set up your environment, of course!
- launch the 'usage' target to verify it

# Troubleshooting

---

## > Tomcat won't start

- JRE\_HOME is set properly?
- do you have TOMCAT\_HOME/**logs** directory?
- what does TOMCAT\_HOME/logs/**catalina.out** report?

## > My web application is not working

- **environment.properties** are set up right? Check with the 'usage' ANT target
- did you **undeploy** / **deploy.as.xxx** after modifying the app?
- browsers do caching! Especially for static HTML pages: clean up the cache!
- is the **web.xml** file a well-formed XML file? Check it (open it in Eclipse and/or see if *catalina.out* reports parsing errors... yes, it's quite a mess, but you can find errors in it)
- tomcat does caching too! **reload** your web app (if you enabled the manager, see the next slide) or **shutdown** and **startup** tomcat again!

## Managing Tomcat

- > Tomcat manager reports information on the deployed modules
  - but you must authenticate first!
  - set up a user for the tomcat manager (modify TOMCAT\_HOME/**conf/tomcat-users.xml** by adding *manager* role and corresponding usernames/passwords: see the file in the *tmp* folder of the TemplateWebapp project)
  - now you can command Tomcat remotely, also via ANT
- > The **Context** element represents a web application
  - each web application is based on its corresponding Web Application Archive (WAR) file, or the directory containing the corresponding unpacked contents, as described in the Servlet Specification (version 2.2 or later).
- > Take a look at what you can do with the manager...
  - search for documentation, tutorials, guides, how-tos, etc...
  - you don't have to learn everything, but just to learn how/where to find it!

extra!

# The deployment descriptor

---

Web applications are configured via the web application deployment descriptor.

## > Declaring welcome files

- The welcome files mechanism allows you to specify a list of files that the web container will use for appending to a request for a (valid) URI that is not mapped to a web component.
- If no welcome file is specified, the Application Server will use a file named `index.XXX`, where `XXX` can be `html` or `jsp`, as the default welcome file.
- If there is no welcome file and no file named `index.XXX`, the Application Server returns a directory listing (by default).

## > Mapping errors to error screens

- when an error occurs during execution of a web application, you can have the application display a specific error screen according to the type of error.
- you can specify mappings between exceptions or HTTP status codes and error pages

# The deployment descriptor

The screenshot shows the Eclipse IDE with the `web.xml` deployment descriptor open. The XML content is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN" "http://java.sun.com/dtd/web-app_2_3.dtd">
<web-app>
  <display-name>TemplateHTML</display-name>
  <description>A template web app just to hold HTML pages</description>
  <!-- === Welcome files ===>
  <welcome-file-list>
    <welcome-file>/welcome.html</welcome-file>
  </welcome-file-list>
  <!-- === Error handling ===>
  <error-page>
    <error-code>404</error-code>
    <location>/errorpages/notfound.html</location>
  </error-page>
</web-app>
```

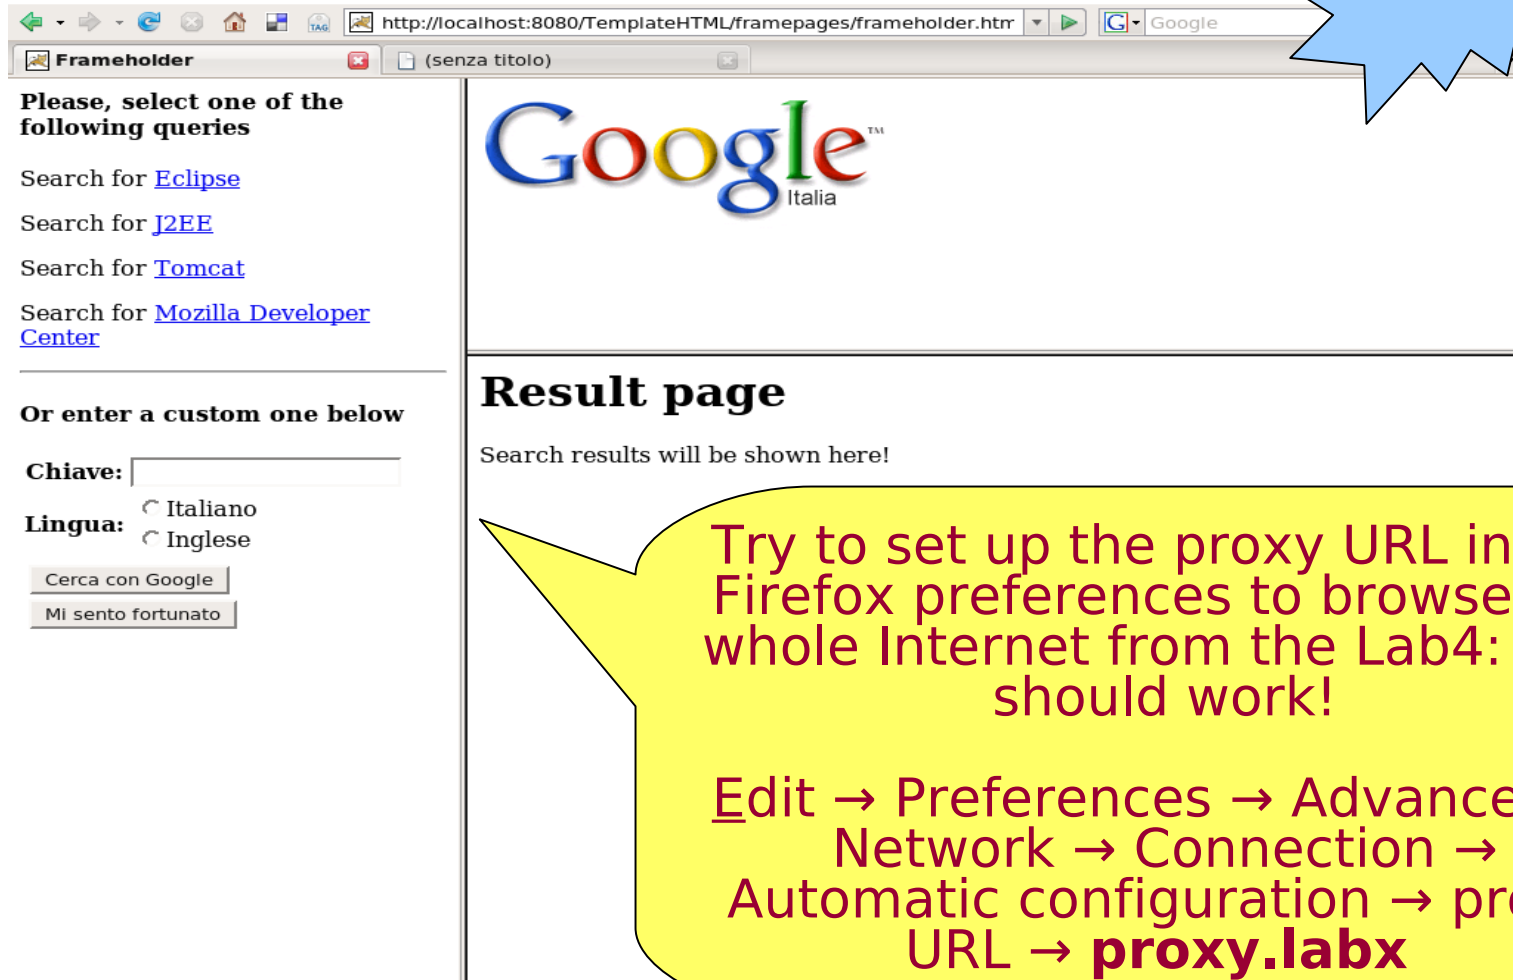

Two browser windows are shown:

- A welcome page - Mozilla Firefox**: Displays the URL `http://localhost:8080/TemplateHTML/` and contains the text:  
Guess, we are about to say...  
Hello world!  
Click [here](#) to go to another page.  
Click [here](#) to go to a non-existing page.
- An error page - Mozilla Firefox**: Displays the URL `http://localhost:8080/TemplateHTML/nowhere.html` and contains the text:  
The resource you requested does not exist.

# Let's add more HTML pages

extra!

Try to do it your self (see friday class!)

**Please, select one of the following queries**

Search for [Eclipse](#)

Search for [J2EE](#)

Search for [Tomcat](#)

Search for [Mozilla Developer Center](#)

---

**Or enter a custom one below**

**Chiave:**

**Lingua:**  Italiano  
 Inglese

---

## Result page

Search results will be shown here!

Try to set up the proxy URL in the Firefox preferences to browse the whole Internet from the Lab4: that should work!

Edit → Preferences → Advanced → Network → Connection → Automatic configuration → proxy URL → **proxy.labx**

# The frameset holder page

---

```
<frameset cols="30%,70%">
  <frame src="search.html"/>
  <frameset rows="30%,70%">
    <frame src="logo.html"/>
    <frame src="results.html" name="results"/>
  </frameset>
</frameset>
<noframes>
<h1>Your browser does not support frames.</h1>
<p>You can find the content by clicking on the following links:
  <ul>
    <li><a href="logo.html">Logo del motore di ricerca</a>;</li>
    <li><a href="search.html">Ricerche predefinite e altro</a>;</li>
    <li><a href="results.html">Risultati della ricerca</a>.</li>
  </ul>
</p>
</noframes>
</frameset>
```

# The logo page

---

> There's no 'google.gif' in the project! We are just refererencing it elsewhere!

- we sniffed the actual location from Google home page source code!

```

```

> Instead, the 'programmer.jpeg' image is a local one.

```

```

+

```

```

> How come images appear and disappear as I move my mouse?

- HTML 4.01 supports events → D(ynamic)HTML
- Events + CSS + Javascript lead to dynamic pages and smart effects, but we can also do something nice just by using DOM !
- It's time to unveil **FireBug!**

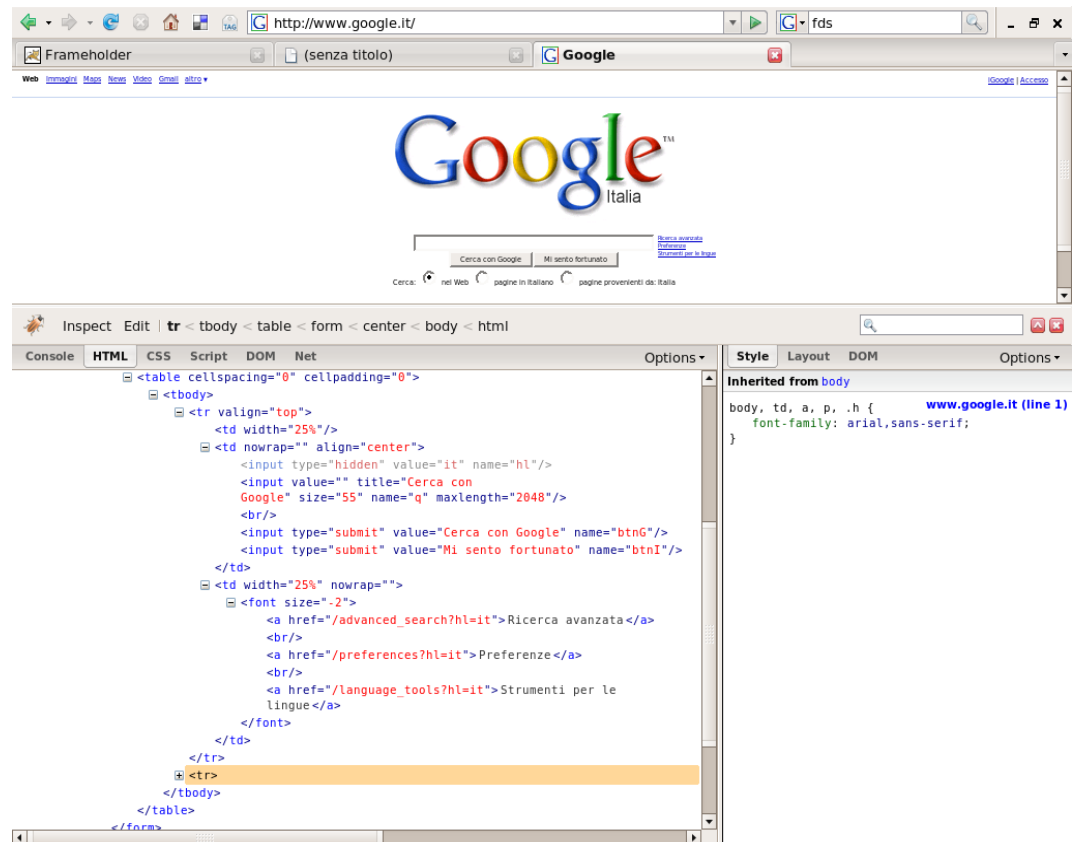

# I can see clearly now...

> We are able to command google searches on our own since **we can see** what happens when we directly perform searches from the Google page!

- We can command searches just by resembling the format of real Google requests

**http://www.google.it/search?hl=it&q=valore&btnG=Cerca+con+Google**

- Google **form** is just a form: we can create one on our own
- Form method is **'GET'** → searches are all about requesting **URIs** → we can also make links to **URIs** representing Google searches!
- Hey! You don't need firebug to see HTML source, anyway!

The image shows a screenshot of a web browser displaying the Google Italia search page. The browser's address bar shows the URL `http://www.google.it/`. The page content includes the Google logo, a search input field, and two buttons: "Cerca con Google" and "Mi sento fortunato". Below the browser window, the developer tools are open, showing the HTML source code of the page. The code is structured as follows:

```
<table cellspacing="0" cellpadding="0">
  <tbody>
    <tr valign="top">
      <td width="25%">
        <td nowrap="" align="center">
          <input type="hidden" value="it" name="hl"/>
          <input value="" title="Cerca con Google" size="55" name="q" maxlength="2048"/>
          <br/>
          <input type="submit" value="Cerca con Google" name="btnG"/>
          <input type="submit" value="Mi sento fortunato" name="btnI"/>
        </td>
      <td width="25%" nowrap="">
        <font size="2">
          <a href="/advanced_search?hl=it">Ricerca avanzata</a>
          <br/>
          <a href="/preferences?hl=it">Preferenze</a>
          <br/>
          <a href="/language_tools?hl=it">Strumenti per le lingue</a>
        </font>
      </td>
    </tr>
  </tbody>
</table>
```

# Behaviour of the links and form page

---

- > **Anchor links** are just hard-coded *URIs*
- > **Form input fields** resembles Google ones (layout is fine thanks to tables!)

```
<h4>Please, select one of the following queries</h4>
```

```
<p>Search for <a target="results" href="http://www.google.it/search?hl=it&q=eclipse">Eclipse</a></p>
```

```
<!-- etcetera... -->
```

```
<hr/>
```

```
<h4>Or enter a custom one below</h4>
```

```
<form action="http://www.google.it/search" method="get" target="results">
```

```
  <table>
```

```
    <tr> <th>Chiave:</th> <td><input type="text" name="q" value=""/></td> </tr>
```

```
    <tr> <th>Lingua:</th> <td>
```

```
      <table><tr><td><input type="radio" name="hl" value="it">Italiano</td></tr>
```

```
      <tr><td><input type="radio" name="hl" value="en">Inglese</td></tr></table></td> </tr>
```

```
    <tr> <td colspan="2">
```

```
      <table><tr><td><input type="submit" name="btnG" value="Cerca con Google"/></td></tr>
```

```
      <tr><td><input type="submit" name="btnI" value="Mi sento fortunato"/></td></tr></table>
```

```
    </td> </tr>
```

```
  </table>
```

```
</form>
```
