Abstract

Despite their dynamic nature, social commitments have been rarely used for monitoring purposes. Few attention has been paid to the relationship between commitments and the temporal dimension and to the corresponding run-time verification. Building on previous work, we present a declarative axiomatization of time-aware social commitments, extending their basic life cycle with time-related transitions and with compensation mechanisms. The formalization is based on a reactive version of the Event Calculus, able to monitor the commitments evolution during a system’s execution, checking if the interacting agents are honoring them or not.

1 Introduction

Social commitments have been increasingly applied to capture normative aspects and interaction protocols in open Multiagent Systems [Yolum and Singh, 2002] and, more recently, to provide declarative abstractions for modeling Business Protocols and Service Oriented Systems. The basic idea is to offer the abstraction of commitment to model, at the social level, the mutual obligations established by the interacting parties: during the interaction, an agent becomes debtor towards a creditor agent to bring about some property. Each execution of the system under study can be characterized in terms of how the involved commitments evolve over time due to the occurrence of events. Such events, generated by the interacting agents, implicitly lead to manipulate commitments, causing them to change state. The state machine of the possible commitment’s states and of the operations associated to state transitions, is called commitment life cycle.

Despite their dynamic nature, social commitments have been rarely used for run-time verification purposes, i.e., for monitoring the system’s executions and track the evolution of mutual obligations, checking if the interacting agents are honoring them or not. We argue that this lack is mainly due to the absence of monitoring frameworks able to capture the commitment’s life cycle and, at the same time, to provide formal guarantees about their operational functioning (such as soundness, completeness and termination).

In the last few years, we have developed a computational logic-based reactive form of Event Calculus (EC)\(^1\), called \(\mathcal{REC}\) [Chesani et al., 2009], which supports the modeling of EC specifications and carries out run-time, dynamic reasoning, computing and reporting back to the user the evolution of fluents caused by the events occurred so far. \(\mathcal{REC}\) is inspired by the Cached EC [Chittaro and Montanari, 1996], for which a theoretical investigation concerning the spatial and temporal complexity has been carried out, attesting that it guarantees a better performance than the classical EC when reasoning upon a growing execution trace. A \(\mathcal{REC}\) specification is obtained by composing a general specification formalizing the calculus with a user-specified knowledge base \(\mathcal{KB}\), made up of a set of Horn clauses relating specific events and fluents (modeling e.g. that a fluent is initiated by a certain event).

In [Chesani et al., 2009], we have discussed the formal properties of \(\mathcal{REC}\), showing that it guarantees soundness, completeness and termination (for the last two properties, provided that \(\mathcal{KB}\) is acyclic [K. R. Apt and M. Bezem, 1990]), and that it generates irrevocable answers when employed for monitoring. We have also described how \(\mathcal{REC}\) can be exploited to perform run-time monitoring of commitment-based interactions, relying on the EC-based formalization of the life cycle proposed in [Yolum and Singh, 2002].

Since commitments evolve over time, the temporal dimension plays a key role and can be further investigated to extend their expressiveness, e.g. to introduce the notion of a deadline by which some commitment must be satisfied. The addition of quantitative temporal aspects in commitments modeling has been first addressed in [Mallya and Huhns, 2003] and then in [Torroni et al., 2009], where \(\mathcal{REC}\) is applied for tracking commitments augmented with temporal constraints, handling their violation and compensation.

In this work, we further develop such a line of research, reconciling the treatment of the time-aware

\(^1\)We assume the reader is familiar with the EC and its ontology [Kowalski and Sergot, 1986].
commitments proposed in [Mallya and Huhns, 2003; Torroni et al., 2009] with the original commitment life cycle formalized in [Yolum and Singh, 2002], suitably extending it to handle the satisfaction and violation of time-aware commitments and to accommodate compensation mechanisms. The REC axiomatization of the extended life cycle brings two main advantages: on the one hand, all the formal properties proven for REC are inherited; on the other hand, time-aware commitment specifications can be directly monitored, relying on the operational counterpart of REC.

The paper is organized as follows. In Section 2, we introduce time-aware commitments and discuss how their life cycle can be extended to deal with them. In Section 3, we propose a REC-based formalization of the extended life cycle. The potentialities and feasibility of our approach are shown in Section 4, by means of an effective example. Conclusion follows.

2 Extending the Commitment Life Cycle

A (base-level) social commitment relates three different entities: a debtor agent, which is committed towards a creditor agent to bring about a property desired by the creditor. By identifying these three entities with $x$, $y$ and $p$ respectively, this kind of commitment is denoted by $C(x,y,prop(p))$, and will be called basic commitment throughout the paper. During the interaction, the events generated by the agents implicitly lead to execute operations on commitments, manipulating them by affecting their status. For the sake of space, we will focus only on the three fundamental operations of create, discharge and cancel applied to base-level commitments. The other operations (such as release, delegate and assign) as well as the treatment of conditional commitments, can be seamlessly introduced in our framework.

2.1 Life Cycle and Compensation

The commitment life cycle targeted in this work is illustrated in Figure 1. At the beginning of execution, the commitment does not exist (or, alternatively, can be considered in a null state). The commitment starts to exist when a create operation is executed, causing a commitment’s transition to the active state: from now on, the debtor agent becomes committed to bring about the involved property. An active commitment makes a further transition when it is manipulated by a discharge or cancel operation. In the first case, the commitment has been honored by the debtor, and the new state is therefore satisfied; in the latter case, a problem or exception occurred, leading to a violation of the commitment.

In addition to these “standard” transitions and states, we also support a further situation, in which the commitment is canceled but a new commitment (called compensating commitment) is created to handle (compensate) the violation, trying to recover it inside the interaction protocol. If the user defines that commitment $c_2$ represents a compensation for commitment $c_1$, the impact of canceling $c_1$ is twofold: instead of becoming violated, $c_1$ makes a transition to the compensated state while, at the same time, $c_2$ is created, becoming active\(^2\).

Let us now focus on the semantics of operations in terms of events and commitments’ status. Operations are always applied in response to the occurrence of a corresponding event. They are partly specified at the domain-dependent level, and partly in a domain-independent fashion. In particular, the creation of a compensating commitment is always defined in terms of the cancelation of the compensated commitment, while the creation of a “normal” commitment is user-defined by means of a domain-specific event. A similar dichotomy exists for the discharge and cancel operation. On the one hand, the semantics of discharge is defined in a domain-independent manner, and states that a commitment is discharged by an event if such an event has the effect of bringing about the commitment’s property; on the other hand, the cancelation of a commitment is caused by the generation of a specific domain-dependent event during the interaction.

2.2 Time-Aware Commitments

This analysis points out a limitation of the basic life cycle: an active commitment which is not explicitly canceled, and whose property is never made true, will continue to persist indefinitely in the active status. It would be then desirable to introduce temporal constraints regulating when the commitment’s property must be made true. To do so, the temporal dimension must be introduced inside the specification of commitments, making them time-aware.

By relying on [Mallya and Huhns, 2003; Torroni et al., 2009], we propose two classes of time-aware commitments, respectively focused on the achievement and maintenance of a certain property:

- $C(x,y,prop(e(t_1, t_2), p)))$ represents an existential commitment, where $x$ is committed to bring about $p$ inside the time interval $[t_1, t_2]$\(^3\);
- $C(x,y,prop(u(t_1, t_2), p)))$ represents an universal commitment, where $x$ is committed to maintain

\(^2\)Other choices could be taken to model the active-compensated transition; for example, a violated commitment could be considered compensated only when the compensating commitment has been satisfied.

\(^3\)A basic commitment can be therefore considered as a special case of existential commitment, where $t_1$ is the time at which the commitment is created, and $t_2 = \infty$. 
Figure 2: Monitoring Framework for Time-Aware Commitments.

\[ p \text{ valid along the whole time interval } [t_1, t_2]. \]

Being the properties involved in such commitments time-dependent, not only their discharge, but also their cancelation, can be defined in a domain-independent manner.

In particular, \( C(x, y, \text{prop}(e(t_1, t_2), p)) \) becomes satisfied an event \( e \) generated at a time \( t \in [t_1, t_2] \), such that \( e \) makes \( p \) true. Conversely, if the existential commitment is still active after \( t_2 \), then \( p \) has not become true inside \([t_1, t_2]\), and therefore the commitment must be canceled due to a violation of the temporal constraints. It is worth noting that \( t_2 \) acts as a deadline by which \( p \) must be brought about to satisfy the commitment.

The case of a universal commitment is the opposite. If \( C(x, y, \text{prop}(u(t_1, t_2), p)) \) is active at a time \( t \in [t_1, t_2] \), and \( p \) is not true at time \( t \), then the validity of \( p \) along the whole interval \([t_1, t_2]\) has been “broken”, and the commitment is violated. Conversely, if the universal commitment is still active after \( t_2 \) then the commitment has not been canceled before, i.e., the validity of \( p \) has been maintained during \([t_1, t_2]\), and therefore the commitment is satisfied.

As we will see later, since all the commitment’s operations are applied when a corresponding event occurs, the actual evaluation of an existential (universal) commitment’s cancelation (discharge) is performed when the first event after \( t_2 \) occurs.

3 Formalizing the Life Cycle of Time-Aware Commitments in REC

We now present how the commitment life cycle described in Section 2 can be formalized in REC. As pointed out in the introduction, a REC theory is a knowledge base \( KB \) composed by a set of Horn clauses which bind together events and fluents. It is worth noting that such a \( KB \) relies on the “standard” EC ontology, making other EC reasoners seamlessly applicable as well. In the case of time-aware commitments, the theory itself is composed by two different knowledge bases, as shown in Figure 2. The first is a domain-independent theory formalizing the life cycle of time-aware commitments; it relates the initiation/termination of the commitments’ status with operations, and defines the domain-independent semantics of operations. The second is a theory representing the specific domain under study; it includes domain-dependent fluents and commitments as well as their relationship with specific events. In this Section we focus on the general formalization of time-aware commitments. An example of domain-dependent theory will be presented in Section 4.

The REC-based axiomatization of time-aware commitments is inspired by [Yolum and Singh, 2002], where EC is employed to provide a formalization of the commitment life cycle. In the EC setting, properties are represented by fluents, whose validity evolve over time as event occurs. Therefore, the concept of “bringing about some property \( p \)” is translated as “initiating fluent \( p \)”, while the validity/truth of \( p \) at a given time is expressed by stating that fluent \( p \) holds at that time.

Beside the introduction of time-aware commitments and their compensation, there is a further difference between the formalization proposed by Yolum and Singh and ours. While in [Yolum and Singh, 2002] commitments are directly mapped onto fluents (initiated through the create operation and terminated by the cancel/discharge operations), we map each commitment’s status to a separate fluent \( \text{status}/2 \), where \( \text{status}(c, s) \) expresses that commitment \( c \) is in state \( s \).

In this way, commitment’s states are reified and can be reported to the user by the monitoring framework, as well as involved in the domain-dependent theory.

Since the knowledge base expressing the extended life cycle is a general theory, all the involved events, agents and properties are variable: their grounding will be defined by the domain-dependent theory, together with the concrete events characterizing the monitored execution of the system under study. The first five axioms characterize the commitment’s life cycle transitions depicted in Figure 1 in terms of the corresponding operations, while the remaining axioms capture the domain-independent semantics of operations, as informally described in Section 2.2.

**Axiom 1 (Status query)** A commitment \( C \) is active/satisfied/violated/compenated at time \( T \) if the corresponding status fluent holds at time \( T \). For example, for the active state we have:

\[
\text{active}(C, T) \leftarrow \text{holds.at}(\text{status}(C, \text{active}), T).
\]

**Axiom 2 (Active state)** A commitment becomes active when it is created by the debtor agent through an event occurrence \( E^3 \):

\[
\text{initiates}(E, \text{status}(C(X, Y, P), \text{active}), T) \leftarrow \text{create}(E, X, C(X, Y, P), T).
\]

The active state is left when the commitment is discharged or canceled by another event occurrence:

\[
\text{terminates}(E, \text{status}(C(X, Y, P), \text{active}), T) \leftarrow \text{discharge}(E, X, C(X, Y, P), T).
\]

\[
\text{terminates}(E, \text{status}(C(X, Y, P), \text{active}), T) \leftarrow \text{cancel}(E, X, C(X, Y, P), T).
\]

\( ^3 \)E.g. to state that a commitment \( c \) is created by event \( e \) if another commitment \( c_2 \) is currently active.

\( ^4 \)If the user wants to state that only the debtor agent \( X \) can perform the operation, a representation for events such as \( e(\text{Responsible}, \text{Content}) \) is needed, binding \( \text{Responsible} \) to \( X \). Similar considerations hold for the other operations.
Axiom 3 (Active-discharged transition) A commitment makes a transition from the active status to the satisfied one when it is discharged by the debtor agent through an event occurrence:

\[
\text{initiates}(E, \text{status}(C(X,Y,P), \text{satisfied}), T) \leftarrow \text{discharge}(E, X, C(X,Y,P), T).
\]

Axiom 4 (Active-canceled transition) Commitment C makes a transition from the active status to the violated one if it is canceled by an event occurring at time T, and no compensating commitment has been defined for C at T:

\[
\text{initiates}(E, \text{status}(C(X,Y,P), \text{violated}), T) \leftarrow \neg \text{compens}(C(X,Y,P), \_T) \land \text{cancel}(E, X, C(X,Y,P), T).
\]

It is worth noting that the definition of compensating commitments is done at the domain-dependent level through the \text{compens}/3 predicate, where \text{compens}(C_1, C_2, T) states that commitment C_1 can be compensated by means of C_2 at time T (i.e., that if a violation of C_1 happens at time T, then C_2 is created as a compensating commitment).

Axiom 5 (Compensation) Commitment C makes a transition from the active status to the compensated one if it is canceled by an event occurring at time T, and a compensation has been defined for C at T:

\[
\text{initiates}(E, \text{status}(C(X,Y,P), \text{compensated}), T) \leftarrow \text{compens}(C(X,Y,P), \_T) \land \text{cancel}(E, X, C(X,Y,P), T).
\]

At the same time, the compensating commitment becomes active:

\[
\text{initiates}(E, \text{status}(C(W,Z,P_2), \text{active}), T) \leftarrow \text{compens}(C(X,Y,P), C(W,Z,P_2), T) \land \text{cancel}(E, X, C(X,Y,P), T).
\]

Axiom 6 (Discharge) An active basic commitment C is discharged by the occurrence of an event if the event brings about C’s property:

\[
\text{discharge}(E, X, C(X,Y, \text{prop}(P)), T) \leftarrow \text{active}(C(X,Y, \text{prop}(P)), T) \land \text{initiates}(E, P, T).
\]

An active existential commitment C is discharged by an event E if E occurs inside the time interval targeted by C and brings about C’s property:

\[
\text{discharge}(E, X, C(X,Y, \text{prop}(e(T_1,T_2), P)), T) \leftarrow \text{active}(C(X,Y, \text{prop}(e(T_1,T_2), P)), T) \land T \geq T_1 \land T \leq T_2 \land \text{initiates}(E, P, T).
\]

A universal commitment is automatically discharged after its targeted time interval if it is still active:\footnote{This means that it has not been canceled in between, attesting that the property has been maintained valid throughout.}

\[
\text{discharge}(E, X, C(X,Y, \text{prop}(u(T_1,T_2), P)), T) \leftarrow \text{active}(C(X,Y, \text{prop}(u(T_1,T_2), P)), T) \land T \geq T_2.
\]

Axiom 7 (Cancel) The cancelation of a basic commitment is user-defined. An existential commitment is automatically canceled after its targeted time interval if it is still active (this means that it has not been discharged before, i.e. the debtor agent has not brought about the property when expected):

\[
\text{cancel}(E, X, C(X,Y, \text{prop}(e(T_1,T_2), P))), T) \leftarrow \text{active}(C(X,Y, \text{prop}(e(T_1,T_2), P))), T) \land T \geq T_2.
\]

An active universal commitment is canceled during its targeted time interval as soon as it is detected that the commitment’s property is not holding:

\[
\text{cancel}(E, X, C(X,Y, \text{prop}(u(T_1,T_2), P))), T) \leftarrow \text{active}(C(X,Y, \text{prop}(u(T_1,T_2), P))), T) \land T \geq T_1 \land T \leq T_2 \land \neg \text{holds_at}(P,T).
\]

4 A Car Rental Example

We now discuss a simple but effective example, which shows the potentialities of time-aware commitments and of the underlying REC monitoring framework.

A contract formalizes the mutual obligations between a customer and an agency when a car is rented; the following statements are included in the contract:

(S1) the customer is committed of taking the car back to the car rental agency within the agreed number of days;

(S2) the agency, in turn, guarantees that the rented car will not break down for the first three days;

(S3) if the rented car breaks down before the third day has elapsed, the agency promises a “1-day” immediate replacement;

(S4) in case of a car replacement, the customer receives two more rental extra-days for free.

To formalize this contract in terms of (time-aware) commitments and enable monitoring, the following steps must be followed:

A. Identification of the events that can be extracted from the car rental agency’s information system.

B. Elicitation of the fluents which characterize the states of affairs of the running system.

C. Binding between events and fluents (i.e., definition of how the events affect fluents through \text{initiates} and \text{terminates} predicates).

D. Elicitation of the commitments formalizing the statements included in the contract (i) using (some of the) fluents identified during step B to represent the “property part”; (ii) introducing existential/universal temporal constraints if needed; (iii) defining their operations (create, discharge, cancel, compensation) in terms of the events identified during step A.

A. Events Identification We suppose that the agency information system collects and stores the events characterizing the evolution of each rental:

- rent\(_{\text{C}}(\text{A, Car, N})\) - customer C rents a car \text{Car} at the agency \text{A} for \text{N} days;

- drive\(_{\text{back}}(\text{C, Car, A})\) - customer C drives \text{Car} back to the agency \text{A};

- break\(_{\text{down}}(\text{Car})\) - Car breaks down;
• replace(A, C, Car_{old}, Car_{new}) - agency A takes back Car_{old} from customer C and substitutes it with Car_{new}.

Beside these domain-dependent events, we also suppose that three further events start, complete and tick are delivered to the monitoring framework. The first two events are used to respectively alert R\&C that the execution has begun/finished; the tick event, instead, is used to inform R\&C about the current time: R\&C itself has no explicit notion of the time flow - it reacts to each incoming event updating the status of fluents and commitments and then waiting until a new event occurs. The delivery of tick events (e.g. by employing an external clock) is then useful to enable the prompt evaluation of temporal constraints by R\&C (see Axiom 7 - first rule, and Axiom 6 - third rule), which in turn permits to determine whether an existential (universal resp.) commitment must be canceled (discharged resp.). If tick events are not employed, such an evaluation is carried out as soon as the first suitable domain-dependent event occurs.

B. Fluents Elicitation The system is characterized by the status of the cars owned by the agency:
• in_{agency}(A, Car) - Car is parked in agency A;
• great_{car}(Car) - Car is working;
• hired(C, Car, D) - Car is being rented by customer C until date D;
• car_{replaced}(Car) - Car has been replaced.

C. Events-Fluents Binding Fluents are affected by the events in the following way. First of all, when a customer rents a car, the car is no more in _agency and becomes hired until the date obtained by the current date plus the chosen number of days:

\[
\text{terminates} (\text{rent}(C, A, Car_{old}, N), \text{in}_{\text{agency}}(A, Car), T) \\
\text{initiates} (\text{rent}(C, A, Car, N), \text{hired}(C, Car, D), T) \leftarrow D = T + N.
\]

When the customer drives back to the agency, the car is no more hired and starts to be in _agency again:

\[
\text{terminates} (\text{drive}_{\text{back}}(C, Car, A), \text{hired}(C, Car, D), T) \\
\text{initiates} (\text{drive}_{\text{back}}(C, Car, A), \text{in}_{\text{agency}}(A, Car), T).
\]

When the car breaks down, it is no more a great car:

\[
\text{terminates} (\text{break}_{\text{down}}(Car), \text{great}_{\text{car}}(Car), T).
\]

When the agency replaces a car, it becomes replaced:
\[
\text{initiates} (\text{replace}(A, C, Car_{1}, \_), \text{car}_{\text{replaced}}(Car_{1}), T).
\]

Furthermore, the replaced car is brought back to the agency, while the new one is carried out from the agency and given to the customer:

\[
\text{initiates} (\text{replace}(A, C, Car_{2}, \_), \text{in}_{\text{agency}}(A, Car_{2}), T) \\
\text{terminates} (\text{replace}(A, C, Car_{1}, \_), \text{in}_{\text{agency}}(A, Car_{1}), T) \\
\text{terminates} (\text{replace}(A, C, Car_{2}, \_), \text{in}_{\text{agency}}(A, Car_{2}), T).
\]

Car’s replacement ceases the hiring of the old car, and causes the new car to be hired. Following the prescription of the contract Statement S4, the new car is hired until the date fixed for the old one plus two extra-days:

\[
\text{terminates} (\text{replace}(A, C, Car_{1}, \_), \text{hired}(C, Car_{1}, D), T) \\
\text{initiates} (\text{replace}(A, C, Car_{1}, Car_{2}), \text{hired}(C, Car_{2}, D), T) \\
\leftarrow \text{holds}_{\text{at}}(\text{hired}(C, Car_{1}, D_{old}), T), D = D_{old} + 2.
\]

D. Commitments Elicitation We now rephrase Statements S1, S2 and S3 in terms of time-aware commitments. Statement S1 is a commitment which is created when the customer rents a car, and is associated to a deadline. The deadline can be expressed by means of an existential temporal constraint imposing that the commitment’s property – “bringing the car back” – must be initiated by the customer between the time at which the commitment is created and the agreed number of days. The property corresponds to the in _agency fluent, while the value of the deadline can be obtained as done for the hired fluent:

\[
\text{create} (\text{rent}(C, A, Car, N), C, \\
\text{C}(C, A, \text{prop}(e(T, T_{e}), \text{in}_{\text{agency}}(A, Car))), T) \leftarrow T_{e} = T + N, \text{holds}_{\text{at}}(\text{in}_{\text{agency}}(A, C), T).
\]

Statement S2 can be represented by an universal commitment, also created when the customer rents a car. Indeed, guaranteeing that the rented car will not break down for three days can be formalized by stating that the great_{car} fluent related to the car should continuously hold for such three days:

\[
\text{create} (\text{rent}(C, A, Car, N), A, \\
\text{C}(A, C, \text{prop}(u(T, T_{e}), \text{great}_{\text{car}}(Car))), T) \leftarrow T_{e} = T + 3.
\]

Finally, Statement S3 refers to a situation in which the commitment introduced by Statement S2 has been violated, and can be therefore formalized as a compensating commitment using the compens/2 predicate. The compensating commitment is existential, and states that the agency is committed to bring about the car_{replaced} fluent within one day from the cancelation of the compensated commitment:

\[
\text{compens}(C(A, C, \text{prop}(u(T_{r}, T_{r})), \text{great}_{\text{car}}(Car))), C(A, C, \text{prop}(u(T_{r}, T_{r}), \text{car}_{\text{replaced}}(Car))), T) \leftarrow T_{r} = T + 1.
\]

4.1 Monitoring Instance

Figure 3 depicts the result computed by R\&C when reasoning upon the formalization of the presented example in a specific case, which captures the interaction between a car rental agency ag and customer ian. A monitoring instance is characterized by a (growing) execution trace collecting all the events occurred so far, and by an initial state, describing which fluents initially hold. In our case, ag has initially two cars in the agency, the initial state is then described by:

\[
\text{initially}_{\text{holds}} (\text{in}_{\text{agency}}(ag, bo123)) \\
\text{initially}_{\text{holds}} (\text{in}_{\text{agency}}(ag, bo124)).
\]

As reported in the bottom part of Figure 3 (considering a day as the time unit), the execution under study models a situation in which ian rents car bo123 from
Figure 3: Sample outcome shown by jREC when reasoning upon the example described in Section 4.

ag, but the car breaks down during the guarantee; a compensation must be therefore handled by ag, which however misses the deadline, replacing the car only after 4 days and causing a violation of the compensating commitment. The commitments having ian as debtor are instead both satisfied: the first due to the replacement of car bo123, the second because ian drives car bo124 back to ag one day before the expected date.

\( \text{REC} \) took a total time of 2.85 seconds to reason upon the entire execution trace on a MacBook Pro Intel CoreDuo 2.66 GHz machine.

5 Conclusion

We have proposed an extended commitment life cycle accommodating time-aware social commitments and their compensation. We have formalized such a life cycle as an EC theory, using a reactive version of EC, called \( \text{REC} \), for monitoring the executions of the system under study, tracking the commitments evolution as events occur. Being the presented theory acyclic, the acyclicity of the domain-dependent theory is a necessary and sufficient condition for ensuring that the monitoring framework is sound, complete and guarantees termination [Chesani et al., 2009].

Alternative formalizations of commitments rely on temporal logics (CTL in particular). \( \text{REC} \) has two main advantages if compared with such approaches: it supports the modeling of data (and conditions) as well as of quantitative time constraints, used to handle time-aware commitments; support is provided at the language and at the operational level. The introduction of deadlines inside a logic combining CTL and deontic aspects has been studied in [Broersen et al., 2004], but the approach is not grounded on a reasoning framework, and deadlines do not refer to time values, but only to the (unknown) time at which a certain property becomes true. To accommodate quantitative time, metric temporal logics should be used, as done in [Mallya and Huhns, 2003]. Our time-aware commitments cover all the cases described there, and can be effectively computed by \( \text{REC} \). A more detailed comparison can be found in [Torroni et al., 2009].

A Java tool called jREC is currently being implemented around \( \text{REC} \). The tool relies on a two-ways integration between SWI Prolog as the reasoning engine for \( \text{REC} \), and a Java-based generic event acquisition module with an event queue. Java is also used to graphically report the outcome dynamically produced by \( \text{REC} \), giving a constantly updated snapshot about the status of fluents and commitments.
